General Description

The AAT2893 family is a highly-integrated lighting management unit (LMU) optimized for single-cell lithium-ion/polymer battery powered systems and is ideal for portable devices.

The AAT2893 integrates a high voltage DC/DC boost converter and an internally programmed over-voltage protection circuit. It drives 10 LEDs (or more) in series controlled by a high precision, 128-step current sink, programmable up to 28.6mA. The high frequency PWM dimming implementation is compliant with Content Adaptive Brightness Control (CABC) specification with a PWM frequency up to 100kHz. The ambient light sensor (ALS) management function features automatic sensor calibration, enabling system designers to use low cost photo diodes, and 50Hz/60Hz noise rejection for accurate brightness adjustment without processor intervention. The AAT2893 also contains four high-performance, low-noise and low dropout (LDO) linear regulators. Each regulator starts up with a default 1.2V and is adjustable by programming through the I2C interface. LDOA can supply up to 300mA, while LDOB, C and D can source up to 150mA to a system load.

All AAT2893 functions are programmed using an industry standard bi-directional I2C interface.

The AAT2893 is available in a Pb-free, space saving 2.0mm x 2.5mm, 20-ball CSP package rated over a -40°C to +85°C temperature range.

Features

WLED Driver

- 1.3MHz Switching Frequency
- Over-voltage Protection
  - AAT2893-1 up to 42V
  - AAT2893-2 up to 33V
- Automatic Soft Start
- Programmable Backlight Current
  - 28.6mA Maximum Current
  - 128 Levels (7-bit): 0 – 28.6mA
- Programmable Fade-in and Fade-out
- Advanced Dimming Features
  - Ambient Light Sensor Management
  - Direct Ambient Dimming Function
    - 128 Programmable Levels
  - CABC Compatible PWM Dimming

Four Linear Regulators

- LDOA up to 300mA
- LDOB, LDOC and LDOD up to 150mA
- 150mV Dropout
- I2C Programmable Outputs: 1.2V to 3.3V
- Output Auto-Discharge for Fast Shutdown

- Input Voltage Range: 3.0V to 5.5V
- Built-In Over-temperature Protection
- Industry Standard I2C Programming Interface
- -40°C to 85°C Temperature Range
- 2.0mm x 2.5mm, 20 Ball, 0.4mm Pitch CSP Package

Applications

- Camera Enabled Mobile Devices
- Digital Still Cameras
- Multimedia Mobile Phones

¹. The AAT2893 is guaranteed to meet performance specifications over the -40°C to +85°C operating temperature range and is assured by design, characterization, and correlation with statistical process controls.

². Current matching is defined as the deviation of any sink current from the average of all active channels.

³. $V_{OVP(RC)}$ is defined as $V_{IN} - LDO(A/B/C/D)$ when $LDO(A/B/C/D)$ is 98% of nominal.

**Functional Description**

The AAT2893 integrates a high voltage DC/DC boost converter and an internally programmed over-voltage protection circuit. It drives up to 10 backlight LEDs in series from a 3.0V to 5.5V input voltage source. To reduce overall power consumption, the AAT2893 supports CABC by providing high frequency filtered PWM for content based dimming and automatic ambient light sensing for varying lighting conditions. The ambient light control (ALC) includes a regulated bias supply to power an ALS or a photo diode. The integrated ADC polls the ambient light conditions and is readable through the I²C interface. The ambient light control (ALC) can also be configured to automatically adjust backlight brightness for changing ambient lighting conditions.

**LED Driver**

The AAT2893 is capable of driving up to 10 backlight LEDs in series with 128 programmable constant current levels up to 28.6mA. The inductive DC/DC boost converter operates at a high, 1.3MHz switching frequency allowing the use of small external 1.0μF-4.7μF ceramic
AAT2893

CABC Compatible, Ambient Light Control Boost LED Backlight Driver and Four LDOs

capacitors and requiring a 4.7μH-22μH inductor. The output of the DC/DC boost converter is controlled by the voltage across the LED current sink when programmed for a desired LED forward current. An over-voltage protection feedback is provided to prevent damage to the LED string or system when an over-voltage event occurs at the output of the boost converter.

LED Current Control
The backlight LED string constant current level is controlled through the I2C interface. The backlight LED current can be set between 0mA and 28.6mA in steps of approximately 0.23mA. All backlight LED functions including fading, ambient light control and constant current levels are programmed through the I2C interface.

Ambient Light Sensing
The AAT2893 ALC circuit provides an interface and control for external ambient light sensor module or photo diode. The system incorporates a programmable sensor voltage bias supply (SBIAS) which may be configured to output 3.0V, 2.8V, 2.7V or 2.6V and may source up to 30mA. The ALS input has a programmable gain amplifier and ADC. The current ambient light level data can be read through the I2C interface for other system functions. When the ALC is enabled to directly adjust the backlight, the 16 internal registers with pre-configured backlight dimming levels are used to profile 16 different ambient lighting conditions. To save power and improve system efficiency, the ALC circuit features manual polling and automatic polling with programmable polling times. Under polling control, the SBIAS regulator, ambient light sensor and ADC circuit are disabled and only enabled for a short period to sample and store the present ambient light value in the ALS digital output read register. The ADC continuously filters out the 50Hz and 60Hz flicker noise from indoor lighting, eliminating the need for a large capacitor at the output pin of the ambient light sensor.

LDO Regulators
The AAT2893 includes four low dropout (LDO) linear regulators. These regulators are programmable through the I2C interface. LDOA is designed to provide load current up to 300mA, and LDOB, C and D are intended for loads up to 150mA respectively. The output voltage of each LDO can be set to one of 16 levels between 1.2V and 3.3V. The LDO regulators turn on/off and regulate output voltage level by programming through the I2C interface. Additionally, the I2C interface allows the LDO regulators to be enabled independently for any combination of output voltages. The LDO regulators require a small 2.2μF (LDOB/C/D) and a 4.7μF (LDOA) ceramic output capacitor for maximized performance and stability. If improved load transient response is required, larger value capacitors can be used without stability degradation.

Serial Programmed Registers
The AAT2893 has 28 registers listed in Table 1:
- Four for backlight enable, control and configuration of fade in/out function
- Twenty-one for ambient light sensor control and configuration
- Three for LDOs control and configuration.

Backlight Current Programming
The backlight string current is disabled by default. The backlight current can be easily configured by using ILED (00h) registers. LED string needs to be enabled by setting BL_EN=1 from BL_ENBLS (01h) register. The current default setting is 19.8mA.

Fade In/Fade Out Programming
The fade in/out function allows LEDs to fade between two programmed current levels in a smooth, logarithmic progression. By default, fade in/out is enabled (bits FADE_EN and FADE_INIT have a default value of 1). The fade in/out function can be disabled by writing FADE_EN =0 in FADE (03h) register. The fade function can be interrupted by writing the FADE_EN bit to 0 when a fade event is in progress. When this happens, the current will abruptly change to the ceiling value programmed in BL<7:0> bits in ILED register. The duration of the fade in/out sequences can be programmed by setting FTIME=1:0> in FADE register. The default fade in/out timing is 1s.

Fade In Function
At initial start up, the LED string turns on with a default value of 19.8mA per channel unless fade in has been specifically programmed. The lower current (floor) is programmed using FLR[3:0] bits in FADE_FLR register. The default is 0.45mA per channel. The higher current (ceiling) is programmed using bits BL [6:0] in ILED (00h) register. Fade in sequence is initiated when FADE_INIT is changed from 0 to 1 in FADE (03h) register.
Fade Out Function

The fade out sequence is initiated when FADE_INIT is changed from 1 to 0 in FADE (03h) register. The floor current will persist until LED string is disabled by writing BL_EN=1 to BL_ENBLS (01h) register.

I²C Serial Interface Protocol

The AAT2893 uses an I²C serial interface to set backlight LED current, LDO on/off and output voltage, as well as other housekeeping functions. The AAT2893 acts only as a slave device. The I²C protocol uses two open-drain inputs: SDA (serial data line) and SCL (serial clock line). Both inputs require an external pull up resistor, typically to the input voltage. The I²C protocol is bidirectional. The timing diagram in Figure 1 shows the typical I²C interface protocol.

Devices on the I²C bus can either be a master or a slave. Both master and slave devices can send and receive data over the bus, the difference being that the master device controls all communication on the bus. The I²C communications begin by the master making a START condition. Next the master transmits the 7-bit device address and a Read/Write bit. Each slave device on the bus has a unique address. The AAT2893’s 7-bit device address is 0x60.

![Figure 1: Typical I²C Timing Diagram.](image-url)
START and STOP Conditions

START and STOP conditions are always generated by the master. Prior to initiating a START, both the SDA and SCL pin are inactive and are pulled high through external pull-up resistors. As shown in Figure 2, a START condition occurs when the master pulls the SDA line low and, after the start condition hold time (t_{H_T_{STA}}), the master strobes the SCL line low. A START condition acts as a signal to devices on the bus that the device producing the START condition is active and will be communicating on the bus.

A STOP condition, as shown in Figure 2, occurs when SCL changes from low to high followed after the STOP condition setup time (t_{SU_{STO}}), by an SDA low-to-high transition. The master does not issue an ACK but releases SCL and SDA.

TRANSFERRING DATA

Addresses and data are sent with the most significant bit first transmitted and the least significant bit transmitted last. After each address or data transmission, the target device transmits an ACK signal to indicate that it has received the transmission. The ACK signal is generated by the target after the master releases the SDA data line by driving SDA low.

Figure 2: I²C STOP and START Conditions;
START: A High “1” to Low “0” Transition on the SDA Line While SCL is High “1”
STOP: A Low “0” to High “1” Transition on the SDA Line While SCL is High “1”.

Figure 3: I²C Address Bit Map;
7-bit Slave Address (A6-A0), 1-bit Read/Write (R/W), 1-bit Acknowledge (ACK).

Figure 4: I²C Register Address and Data Bit Map;
8-bit Data (D7-D0), 1-bit Acknowledge (ACK).
Writing to Slave Device

When the Read/Write bit is set to 0 and the address transmitted by the master matches the slave device’s address, the slave device transmits an Acknowledge (ACK) signal to indicate that it is ready to receive data. Next, the master transmits the 8-bit register address, and the slave device transmits an ACK to indicate that it received the register address. After that, the master transmits the 8-bit data word, and again the slave device transmits an ACK indicating that it received the data. This process continues until the master finishes writing to the slave device at which time the master generates a STOP condition.

Reading from Slave Device

When the Read/Write bit is set to 1 and the address transmitted by the master matches the slave device’s address, the slave device transmits an Acknowledge (ACK) signal to indicate that it is ready to receive data. Next, the slave device transmits the 8-bit data word, and the master reads the data byte and transmits an Acknowledge ACK to indicate that it received the byte, and generates a STOP condition.
**Serial Programmed Registers**

Application Information

Ambient Light Sensor (ALS)

An ambient-light sensor is used to measure the brightness of the surrounding environment. Based on the brightness level, the AAT2893 can adjust the backlight LED current, leading to longer battery life and comfortable viewing with less eyestrain. The AAT2893 supports a wide range of sensors, presently on the market, and performs the gain-adjustment function to correct the part-to-part output variation of an ambient light sensor.

Some typical values of the luminance in different environments are given below as reference points:

- Moonlight: 0.2 to 1 Lux
- Candlelight: 5 Lux
- Streetlight: 10 Lux
- Office light: 300 to 1000 Lux
- Daylight (not direct sun): 10,000 Lux
- Direct sunlight: 100,000 Lux

Ambient light sensors used in smart phone applications are often placed underneath a light pipe and a glass cover. The actual light brightness reaching the ambient light sensor must be determined before choosing an ambient light sensor.

Ambient Light Sensor Selection

The types of ambient light sensors on the market include photodiodes, photo-transistors, and photo-ICs; all these types of sensors generate current or voltage output signals. Ambient light sensors with current outputs require a resistor placed at the output to convert the current into voltage. Figure 20 shows the current output, which is linear or logarithmic with the light brightness in Lux, of an ambient light sensor. Some ambient light sensors provide logarithmic or square-root outputs. If an ambient light sensor with linear output is used while a logarithmic output is desired, the AAT2893 can convert a linear ALS output to logarithmic output by setting SNSR = 0 and setting ALSOUT = 1 in register ALS_CFG2(07h) as shown in Figure 14.

Ambient Light Sensor Evaluation

Determine the Range of Light Brightness that Reaches Ambient Light Sensor (ALS)

Determine the Type of Ambient Light Sensor (ALS)-Linear or Logarithmic

Figure 20: Ambient Light Sensor with Linear or Logarithmic Output Current.

Ambient Light Sensor Evaluation:
1. Select Gain resistor Set
2. Measure DC Offset
3. Select SBIAS Voltage
4. Determine the LED Current For Each Brightness Reading
5. Measure Gain Adjustment

Determine the Backlight Brightness Measurement Mode-Line-Linear or Logarithmic

Determine the Polling Time and Mode – Automatic or Manual

Figure 21: Ambient Light Sensor Configuration Flowchart.
**Ambient Light Sensor Gain Resistor Selection**

When an ambient light sensor with current output is selected, a load resistor is used to convert the output current into an output voltage. The AAT2893 provides a set of 6 internal resistor pairs that are listed in Figure 12. An external resistor can be used if none of the integrated resistor pairs fit the application requirement.

**Example 1:** The light luminance of the ambient light sensor is from 0 Lux to 10,000 Lux. If the output current of an ambient light sensor is 4μA per 100Lux, the resistor required to cover the whole luminance range can be calculated as follows:

\[
\text{Low-gain Resistor} = \frac{V_{\text{AMB IN (MAX)}}}{\frac{4\mu\text{A}}{100\text{Lux}} \cdot 10000\text{Lux}} = 4k\Omega
\]

The chosen resistor set is 4kΩ, 16kΩ.

**Ambient Light Sensor Offset Adjustment**

Any leakage current present will cause an offset at the output of the ambient light sensor, leading to inaccurate measurement of the light brightness. This offset can be corrected by programming bits OS_ADJ<3:0> in register ALS_CFG1 (06h) of the AAT2893. The four allocated bits provide offset correction from -8LSB to +7LSB, as shown in Figure 13.

The DC offset of the ambient-light sensor output can be measured with the AAT2893. The AAT2893 is powered up and enabled with a power supply or a battery; the ambient light sensor is then enabled by writing ALS_EN = 1 to the ALS_CFG0 (05h) register (see Figure 12). The voltage bias for the ambient light sensor needs to be enabled as well by writing SB_EN = 1 to the ALS_CFG1 (06h) register (see Figure 13). The test mode of the ambient light sensor offset commences when writing OFF_TM = 1 to the ALS_CFG1 (06h) register.

**Example 2:** The procedure to determine the ambient light-sensor offset is explained below, assuming a resistor set of 4kΩ, 16kΩ is used:

- Connect the SBIAS pin of the AAT2893 to the input voltage pin of an ambient light sensor, and connect the AMB_IN pin of AAT2893 to the output pin of the ambient-light sensor.
- The BH1600FVC ambient light sensor from Rohm is used with the AAT2893 demo board (Figures 30 and 31). Depending on how much light goes through the light pipe and reaches the ambient light sensor, the GC1 and GC2 setting can be determined. If the range of light is up to 10,000 Lux, the L-Gain mode should be chosen by connecting GC1 to GND and GC2 to SBIAS. If the range of light is up to 3,000 Lux or lower, then the H-Gain mode should be chosen by connecting GC1 to SBIAS and GC2 to GND. The difference between H-Gain mode and L-Gain mode is the amount of output current from the ambient light sensor (see Table 6).
CABC Compatible, Ambient Light Control Boost LED Backlight Driver and Four LDOs

- The AAT2893’s ambient light sensor amplifier is set to auto gain mode. The part will automatically choose the 4kΩ low-gain resistor when the ambient light is bright and the 16kΩ high-gain resistor when the ambient light is dim for better accuracy.
- Set enable pin EN = High and PWM = High to enable the AAT2893.
- Start ambient light sensor offset measurement by writing the following commands to the AAT2893:
  1. Write AAT2893 7-bit I²C address: 0x60 (first byte writes as C0h, binary 11000000).
  2. Enable backlight channel by writing to register BL_EN (01h) data 02h.
  3. Choose linear ambient light sensor gain mode and internal gain resistor pair by writing to register ALS_CFG0 (05h) data 31h.
  4. Enable SBIAS in offset test mode by writing to register ALS_CFG1 (06h) data 81h (Note: During normal operation, offset test-mode should be turned off by setting bit OFF_TM = 0 in ALS_CFG1 (06h) register as shown in Figure 13).
- Read the AMB (08h) register for the ambient light sensor output offset. AMB register has eight bits, only bits AMB[7:3] should be captured; bit AMB[7] is a sign (+ or -) bit.
- Convert the 5-bit in AMB(08h) register in test mode to a 4-bit offset according to Table 3. The 4-bit offset with opposite sign needs to be written to OS_ADJ<3:0> from ALS_CFG1 (06h) register during normal operation. Note: If the 5-bit offset reading is F8h (binary 11111000), then the output offset of the ambient light sensor is -1LSB. It can be converted to 1111 in 4 bits. In order to adjust this ambient light sensor offset, a +1 LSB offset needs to be added, by writing 0001 to OS_ADJ<3:0> of the ALS_CFG1 (06h) register during normal operation. For complete list of offset adjustments see Table 2.

Offset too high
Ambient Light Sensor Gain Adjustment

For the majority of ambient light sensors, the part-to-part variation of the output current is guaranteed to be ±20% at best. More expensive ambient light sensors can guarantee ±10% output accuracy. Tolerances in light pipes and ambient light sensors limit the output current accuracy to only ±35%. AAT2893 allows the customer to choose an inexpensive ambient light sensor while offering a ±10% part-to-part variation by providing an automatic calibration gain adjustment from -50% to +43.75% for any off-the-shelf ambient light sensor. Figure 23 shows the ideal ambient light sensor output versus light brightness after gain-adjustment calibration.

The maximum AMB_IN input voltage is 2.4V with -37.5% gain adjustment. For optimal performance, the minimum output voltage of an ambient light sensor needs to be higher than the adjusted AMB_IN input voltage with an extra 6.25% headroom, or 2.55V according to Table 4.

Ambient Light Sensor Voltage Bias

The external ambient light sensor is powered by the SBIAS output, which is a programmable linear voltage regulator that provides up to 30mA for the sensor bias. The SBIAS output voltage may be programmed and enabled both by the ambient light sensor control register ALS_CFG0 (Figure 12) and the ambient light sensor voltage bias control register ALS_CFG1 (Figure 13). The SBIAS voltage can be selected from 2.6V up to 3V by writing bits SB<1:0> of the ALS_CFG1 (06h) register.

The SBIAS voltage is determined based on the full-scale negative gain adjustment necessary to achieve optimal performance. The relationship between the AMB_IN ideal Full-Scale voltage (unadjusted Full-Scale), the gain adjustment (Gain_ADJ), and the adjusted AMB_IN scale (Adjusted Full-Scale) can be expressed by the following equation:

\[
\text{Adjusted Full-Scale} = \frac{\text{Ideal Full-Scale}}{1 + \text{Gain_ADJ}}
\]

The minimum saturated output voltage of the BH1600FVC ambient light sensor is 2.6V for 3.0V supply voltage; therefore, a SBIAS voltage of 3V should be selected for this particular case. If the calculated AMB_IN maximum voltage exceeds 3V, an external voltage source is recommended.

Table 4: Ambient Light Sensor Gain Adjustment.

**Backlight LED Current Settings for Different Brightness Readings**

The main recipient of the light emitted by all visible spectrum LEDs is the human eye. It responds to light luminance in a non-linear, logarithmic way. The sensitivity of the human eye decreases rapidly as the luminance of the source increases. The LED current needs to change logarithmically in relation to the light brightness in order for the light brightness to be perceived linearly by the human eye.

The AAT2893 has sixteen default LED current setting levels programmed in ALSn (from 09h to 18h) registers. These sixteen current level settings follow the logarithmic trend shown in Figure 24. A linear ambient light sensor output and a linear output brightness are set by using the default setting of SNSR=0 and ALSOUT=0 of the ALS_CFG2 (07h) register. For each light brightness sampling, one of the current levels corresponding to the ambient light reading will be selected to control the backlight LED current. If the desired current settings are different than the default, the user can change them by writing to ALSn (09h through 18h) registers.

![Figure 24: Backlight LED Current vs Light Brightness.](image-url)
Ambient Light Sensor Brightness Gain Mode
AAT2893 allows automatic and manual modes for measurement of the ambient light sensor brightness. The automatic gain mode is selected by default value GM_SEL = 0 in ALS_CFG0 (05h) register. For better accuracy during automatic mode, the AAT2893 will choose low gain resistor when the ambient light is bright and high gain resistor when the ambient light is dim. For the manual gain mode, all light brightness measurements are completed with the low gain resistor as set by GM_SEL = 1 of the ALS_CFG0 (05h) register.

Ambient Light Sensor Brightness Polling Time
The AAT2893 offers two bits for programming the ambient light sensor brightness polling time. There are four different polling times: 0.5s, 1s, 1.5s and 2s selected by writing PTIME<1:0> bits of the ALS_CFG2 (07h) register.

If an automatic ambient light sensor polling mode is selected by default PMODE = 0 of ALS_CFG0 (05h) register, the AAT2893 will periodically update the information about the surrounding brightness at an interval of every elapsed time. Refer to Figure 22 for A/D conversion timing diagram. Manual ambient sensor polling mode can also be selected by writing PMODE = 1 to ALS_CFG0 (05h) register.

\]

Setup Description:
Ambient light sensor model BH1600FVC from Rohm is used with the AAT2893 demo board (Figures 30 and 31). The demo board jumper P3 controls the gain setting GC2 and jumper P4 controls the gain setting GC1. Pin 1 (logic 1) on the jumpers P3 and P4 is designated by the square pad in Figure 28.

- Select low gain ALS output (GC1 = 0, GC2 = 1)
- Backlight LED Current=28.6mA is selected, or doesn’t need to be set
- Resistor set of 4KΩ, 16KΩ is calculated for the application
- Enable Backlight channel. (BL_EN = 1)
- Ambient light sensor has no DC offset
- Ambient light sensor gain adjustment is -18.75%
- Linear ALSOUT and SNSR are selected
- SBIAS = 3.0V is selected
- Enable Ambient Light Sensor. (ALS_EN = 1)
- Light brightness is measured at 1s time intervals
- Read register AMLRB (08h).
Default settings are used for ALS_BLn (09h to 18h) registers.

The following commands need to be communicated to the AAT2893 through the I²C interface:

- Write AAT2893 7-bit I²C address: 0x60 (first byte writes as C0h; binary 11000000)
- Write to register BL_ENBLS (01h) data 02h
- Write to register ALS_CFG0 (05h) data 31h
- Write to register ALS_CFG1 (06h) data 01h
- Write to register ALS_CFG2 (07h) data 1Dh
- Read register AMLRB (08h); bits AMB[7:0] indicate the ambient light brightness level; first byte writes as C1h; all readings are listed in Table 8. AMB[7] is the sign (+ or -) bit.

**Eq 2:**

**Setup Description:**

Ambient light sensor model BH1600FVC from Rohm is used with the AAT2893 demo board (Figures 30 and 31). The demo board jumper P3 controls the gain setting GC2 and jumper P4 controls the gain setting GC1.

- Select high gain ALS output (GC1 = 1, GC2 = 0) (see Table 11).
- Resistor set of 4kΩ, 16kΩ is calculated for the application
- Enable backlight channel (BL_EN = 1)
- Ambient light sensor has no DC offset
- Ambient light sensor gain adjustment is -18.75%
- Logarithmic ALSOUT and Linear SNSR are selected
- SBIAS = 3.0V is selected
- Light brightness is measured at an interval of 1s time
- Read register AMLRB (08h)
- Write to registers ALS_BLn (09h to 18h) the data

The following commands need to be communicated to AAT2893 through I2C:

- Write AAT2893 7-bit I2C address: 0x60 (binary 11000000; first byte writes as C0h)
- Write to register BL_ENBLS (01h) data 02h
- Write to register ALS_CFG0 (05h) data 31h
- Write to register ALS_CFG1 (06h) data 01h
- Write to register ALS_CFG2 (07h) data 5Dh
- Read register AMLRB (08h); bits AMB[7:0] indicate the ambient light brightness level; first byte writes C1h; all readings are listed in Table 15.
- Write to register ALS_BL0 (09h) data 16h
- Write to register ALS_BL1 (0Ah) data 1Bh
- Write to register ALS_BL2 (0Bh) data 1Fh
- Write to register ALS_BL3 (0Ch) data 24h
- Write to register ALS_BL4 (0Dh) data 28h
- Write to register ALS_BL5 (0Eh) data 2Ch
- Write to register ALS_BL6 (0Fh) data 31h
- Write to register ALS_BL7 (10h) data 35h
- Write to register ALS_BL8 (11h) data 3Ah
- Write to register ALS_BL9 (12h) data 3Eh
- Write to register ALS_BLA (13h) data 43h
- Write to register ALS_BLB (14h) data 47h

- Write to register ALS_BLd (16h) data 50h
- Write to register ALS_BLE (17h) data 54h
- Write to register ALS_BLf (18h) data 59h
Content Adaptive Brightness Control (CABC)

The CABC response to an external PWM signal is set by the filter capacitor, $C_{FLTR}$, connected to the FLTR pin. In order to select $C_{FLTR}$ properly, three conditions need to be known:

1. PWM signal frequency at the PWM pin
2. The desired rate of change of the backlight current from one level to another
3. The minimum PWM duty cycle.

The capacitor ($C_{FLTR}$) connected to the FLTR pin has an internal resistor $R_F = 73.3 \, \Omega$ in parallel with ground. The filter capacitor $C_{FLTR}$ pin is charged with a 20μA current source that is modulated with the PWM duty cycle. Refer to Figures 25 and 26 for circuit and timing diagrams.

The value for $C_{FLTR}$ can be calculated with the following equation:

$$C_{FLTR} = \frac{t_F}{3 \cdot R_F \cdot \ln\left(\frac{D0}{D1}\right)}$$

Where,

- $D0$ is the PWM Duty Cycle before the adjustment
- $D1$ is the PWM Duty Cycle after the adjustment.

If the selected $C_{FLTR}$ capacitor value is smaller than 5nF, then the ripple appearing on the backlight PWM current will increase. For external PWM signals equal or lower than 10% duty cycle, the bottom level of the ripple can cause the internal comparators to trip and as a result, the part will switch to a maximum duty cycle of 97.8% for a few clock periods.

If the selected $C_{FLTR}$ value is large, the ripple on the backlight PWM current will be reduced, but it may not be possible to achieve a fast change ($t_F$) of the backlight current level or the desired duty cycle. Table 16 shows the recommended $C_{FLTR}$ Value for Different $t_F$.

If the CABC function is not desired it can be disabled by changing bit CABC from 0 to 1 in BL_ENBLS (01h) register. The AAT2893 will operate with a maximum duty cycle of 97.8% and the $C_{FLTR}$ capacitor is not necessary.

DISCONTINUED
**Note:** A small value $C_{FLTR}$ will result in faster transition time ($t_F$) between current levels but is limited to 5nF by the backlight PWM current ripple.
CABC Compatible, Ambient Light Control Boost LED Backlight Driver and Four LDOs

LED Selection

The AAT2893 is specifically designed for driving white LEDs in TFT-LCD backlighting applications but the device design allows the AAT2893 to drive most types of LEDs with forward voltage specifications ranging from 2.0V to 4.7V. LED applications may include mixed arrangements for display backlighting, color (RGB) LEDs, infrared (IR) diodes or any other load needing a constant current source generated from a varying input voltage.

The low-dropout current sinks in the AAT2893 maximize performance and make it capable of driving LEDs with high forward voltage.

Driving 11 WLEDs Application

The maximum number of WLED depends on the OVP of the AAT2893 part and the forward voltage \( V_f \) of WLED. The OVP of AAT2893-1 is 42V, to a general WLED with about 3.3V forward voltage, it means AAT2893 has ability to drive more than 10 LEDs in series. Figure 27, 28 and 29 show the efficiency, PWM duty vs WLED current and WLED current at different input voltage when AAT2893 drive 11 WLEDs.

Inductor Selection

Inductor value, saturation current and DCR are the most important parameters in selecting an inductor for the AAT2893.

The suitable inductance range for the AAT2893 is 4.7μH to 22μH. Higher inductance lowers the step-up converter’s RMS current value. Together with lower DCR value of the inductor, it makes the total inductor power loss become much lower. Considering inductor size and cost, 4.7μH inductance is most suitable.

Considering the inductor copper loss, the inductor DCR value together with the RMS current flowing through the
CABC Compatible, Ambient Light Control Boost LED Backlight Driver and Four LDOs

Inductor leads to inductor conduction loss and also affects total efficiency. Larger DCR leads to larger conduction loss and reduces total efficiency. The inductor conduction loss can be estimated using the following equation:

\[ P_{L_{\text{LOSS}}} = I_{L_{\text{RMS}}}^2 \cdot DCR = \frac{(I_{L_{\text{MAX}}}^2 + I_{L_{\text{MIN}}}^2 + I_{L_{\text{MAX}}} \cdot I_{L_{\text{MIN}}}) \cdot DCR}{3} \]

Where \( I_{L_{\text{MAX}}} \) and \( I_{L_{\text{MIN}}} \) are the inductor peak current and minimum current respectively.

Inductor saturation current is also a key parameter in selecting an inductor. For the step-up converter, the peak inductor current is the DC input current plus half the inductor peak-to-peak current ripple.

DC input current:

\[ I_{\text{IN}} = \frac{V_{\text{OUT}} \cdot I_{\text{LED}}}{V_{\text{IN}} \cdot \eta} \]

Inductor peak-to-peak current ripple:

\[ I_{L_{\text{PP}}} = \frac{V_{\text{IN}} \cdot (V_{\text{OUT}} - V_{\text{IN}})}{V_{\text{OUT}} \cdot L \cdot f} \]

Inductor peak current:

\[ I_{L_{\text{PEAK}}} = I_{\text{IN}} + \frac{I_{L_{\text{PP}}}}{2} = \frac{V_{\text{OUT}} \cdot I_{\text{LED}}}{V_{\text{IN}} \cdot \eta} + \frac{V_{\text{IN}} \cdot (V_{\text{OUT}} - V_{\text{IN}})}{2 \cdot V_{\text{OUT}} \cdot L \cdot f} \]

For example, for a white LED with 3.2V \( V_f \), 20mA current, 81% efficiency and \( V_{\text{IN}} \) less than 3.6V, the inductor peak current is:

\[ I_{L_{\text{PEAK}}} = \frac{3.6 \cdot 0.8 \cdot 0.02}{3.6 \cdot 0.81} + \frac{3.6 \cdot (3.2 \cdot 0.8 - 3.6)}{2 \cdot 3.2 \cdot 8 \cdot 10\mu \cdot 1\text{M}} = 330\text{mA} \]

**Compensation Component Selection**

A compensation capacitor \( C_{\text{COM}} \) is used for step-up converter loop compensation and soft startup time control. Loop compensation requires matching values for \( C_{\text{COM}}, C_{\text{OUT}}, I_{\text{LED}}, \) and \( V_{\text{OUT}} \):

\[ \frac{C_{\text{OUT}}}{C_{\text{COM}}} < \frac{I_{\text{LED}}}{30 \cdot 10^6 \cdot V_{\text{OUT}}} \]

For example, considering the worse case of AAT2893 driving 10 white LEDs with forward voltages 4V, a \( C_{\text{OUT}} \) value of 1\( \mu \)F, and LED maximum current of about 30mA, the value of \( C_{\text{COM}} \) should be higher than 40nF.

\[ \frac{C_{\text{COM}}}{C_{\text{OUT}}} > \frac{(C_{\text{OUT}} \cdot 30 \cdot V_{\text{OUT}})}{I_{\text{LED}}(\text{nF})} = \frac{(1 \cdot 30 \cdot 40)}{30(\text{nF})} = 40(\text{nF}) \]

A higher value for \( C_{\text{COM}} \) lengthens the soft startup time. So to balance the startup time and the loop stability, 56nF is selected. The relationship between \( C_{\text{COM}} \) and startup time is almost linear, with startup time \( x \) 105 magnification of \( C_{\text{COM}} \); thus 56nF \( C_{\text{COM}} \) leads to a soft startup time of 5.6ms. Values of 56nF for \( C_{\text{COM}} \) and 1\( \mu \)F for \( C_{\text{OUT}} \) are suitable in most cases.

**Schottky Diode Selection**

To achieve maximum efficiency, a low \( V_f \) Schottky diode is recommended. For an AAT2893 driving 10 white LEDs with up to 4V forward voltage, the diode voltage rating should be higher than 40V. Selecting a diode with DC rated current being equal to the input current allows an adequate margin for safe use.

**Printed Circuit Board Layout Recommendations**

Boost converter performance can be adversely affected by poor layout. Possible impact includes high input and output voltage ripple, poor EMI performance, and reduced operating efficiency. Every attempt should be made to optimize the layout in order to minimize parasitic effects on PCB (stray resistance, capacitance, and inductance) and EMI coupling at the high frequency switching node. A suggested PCB layout for the AAT2893 is shown in Figures 31. The following PCB layout guidelines should be considered:

1. Place the input and output decoupling capacitors \( C_1, C_3, C_5, C_2, C_4, C_8, C_9 \) as close to the chip as possible to reduce switching noise and output ripple.
2. Keep the power traces (GND, LX VOUT and VIN) short, direct, and wide to allow large current flow. Place sufficient multiple-layer pads, when needed, to change the trace layer.
3. Maintain a ground plane and connect to the IC PGND pin(s) as well as the PGND connections of \( C_{\text{IN}} \) and \( C_{\text{OUT}} \).
Schematic and Layout
